Control Of Pyrotechnic Burn Rate

One mechanism, useful in adjusting pyrotech- nic output, is the control of burn rate. Burn rate determines the rate of energy release, and thus to some extent the flame temperature of a star. More directly, burn rate determines the rate of gas pro- duction from a propellant, and thus the thrust from and internal pressure within a rocket motor.

Control of Pyrotechnic Burn Rate

An earlier version appeared in Second International Symposium on Fireworks (1994). Control of Pyrotechnic Burn Rate B. J. and K. L. Kosanke ABSTRACT There may be many times when a fireworks manufacturer will want to adjust the burn rate of pyrotechnic compositions. Sometimes this may be for matters of esthetics and other times for safety. For example, all of the following are unacceptable:

monly used. Linear burn rate can be defined as the distance the burning surface of a pyrotechnic composition advances inwardly (perpendicular to the burning surface) per unit time, and typically would be reported as inches per second (or mm/s). Even for a specific pyrotechnic material with a defined composition (including prescribed particle size and shape) there are a number of factors that will affect its burn rate.[1] Generally the most im-

Ferrotitanium – iron-titanium alloy, produces bright yellow-white sparks, used in pyrotechnic stars, rockets, comets, and fountains; Ferrosilicon – iron-silicon alloy, used in some mixtures, sometimes replacement of calcium silicide; Manganese – used to control burn rates, e.g. in delay compositions

Pyrotechnic composition - Wikipedia

The propellant burn rate is the rate at which the exposed propellant surface is consumed. (It is measured as distance normal to surface consumed in a given time.) Solid Rocket Motor Definitions: Burn Rate Coefficient: a Burn Rate Exponent: n Typical Values: 0.05–2 in/s Important: Burn rates are determined in sub-scale firing.

To measure the net burn rate in this timeframe, subtract your cash balance at the end of the quarter from your cash balance at the beginning of the quarter, then divide that number by three (for each month in the quarter). To measure the gross burn rate for the same period, divide quarterly expenses by three.

The answer lies in the chemical composition used to control color and heat and its particle morphology to control the burn rate. Kosanke and Kosanke show that burn rate increases (burn time decreases) with finer meshed particles (Figure 1) and with irregular shapes (Figure 2) 1, both of which control the surface area to volume ratio. Figure 1.
